ABSTRACT

Background and Objectives: Essential oils (EOs) with different biological activities, such as antibacterial properties, are a valuable resource for developing new drugs.

Materials and Methods: Ingredients of six medicinally important EOs, including Artemisia dracunculus, Anethum graveolens, Citrus limon, Citrus sinensis, Cinnamomum zeylanicum and Zingiber officinale, were identified using GC-MS analysis. Moreover, their five major compounds were also listed. Furthermore, the half-maximal inhibitory concentration (IC50) against four important human bacteria was also investigated using the 96-well plate microdilution.

Results: C. sinensis EO with IC50 of 1.0 and 4.7 mg.mL−1 have the most effect on the growth of S. aureus and P. aeruginosa. Moreover, EOs of Cinnamomum zeylanicum (IC50 1.0 mg. mL−1) and Artemisia dracunculus (IC50 1.3 mg.mL−1) significantly showed better inhibitory effect on E. coli and K. pneumoniae.

Conclusion: These EOs could be used for developing inexpensive, potent, and green antibacterial agents.

Keywords: Essential oil; Antibacterial activity; Pathogens; Microdilution

INTRODUCTION

Essential oils (EOs) are a concentrated mixture of hydrophobic compounds in the oil phase, characterized by a strong odor (1). They are secreted as secondary metabolites from different parts of aromatic plants, such as flowers, fruits, seeds, stems, and roots (2). Hydrodistillation using the Clevenger type apparatus is the most common approach for the extraction of EOs (3). Recently, a growing number of studies on different medical properties of EOs have been being performed (4). For example, as flavorings in the food (5), larvicidal activity (6), anticancer drug discovery (7), antioxidant properties (8), and antifungal bioassays (9). In addition to such uses, EOs possess antibacterial effects against human pathogens such as Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa and Klebsiella pneumoniae (10, 11).

In the past, antibacterial properties were mainly reported by minimum inhibitory concentration (MIC) which is described as the lowest concentration of an agent to prevent bacterial visible growth (12). For instance, the MIC of Artemisia dracunculus EO on S. aureus was 62.4 mg.mL−1 (13). Besides, Anethum graveolens EO showed a good antibacterial effect on E. coli with MIC of 2.5 mg.mL−1 (14). However, by developing optical density (OD) dependent techniques, the growth of microorganisms was observed as turbidity, determined by analytical instruments (15).

By investigating the antibacterial activity of active agents at various concentrations and using software such as CalcuSyn, half-maximal inhibitory concentration (IC \textsubscript{50}) is measurable. This value is defined as observing a 50% decrease in bacterial growth in the treated sample compared to the control group. It is a reliable and quantitative unit with upper and lower confidence limits (16).

In this study, ingredient and antibacterial activities of six EOs, including Artemisia dracunculus (ADEO), Anethum graveolens (AGEO), Citrus limon (CLEO), Citrus sinensis (CSEO), Cinnamomum zeylanicum (CZEO), and Zingiber officinale (ZOEO) were investigated. Then for the first time, their IC\textsubscript{50}s were calculated.

**MATERIALS AND METHODS**

**Materials.** Standard species of bacteria, including S. aureus (ATCC 25923), E. coli (ATCC 25922), P. aeruginosa (ATCC 27853), and K. pneumoniae (ATCC 13883) were provided by the laboratory of microbiology, Fasa University of Medical Sciences (FUMS). ADEO was bought from Zardband Pharmaceutical co, Iran. Barij Essence Pharmaceutical Co, Iran, provided AGEO and CLEO. Moreover, Green Plants of Life Co, Ltd, Iran, supplied CSEO, CZEO, and ZOEO. Muller Hinton Broth (Bacterial culture media) was purchased from Merck Chemicals, Germany.

**The procedure of GC-MS analysis.** For the identification of ingredients of the EOs, GC-MS analysis was used. Briefly, The GC-MS analyses were performed using a 7890A Network GC system coupled with 5975C VL MSD with Triple-Axis, mass selective detector (Agilent Technologies, Santa Clara, CA, USA). The separation of the components of the EOs was carried out on HP-5MS silica fused columns (30 m length; 0.25 mm i.d.; and 25 μM film thickness). The GC-MS column temp was programmed as follows: the initial temp was set at 40°C and fixed for 1 min, then increased with the rate of 3°C.min\textsuperscript{-1} to the final temperature of 250°C and held for 20 min. Temperature of the injection port and detector fixed at 250 and 230°C, respectively. Other instrument parameters were set as split flow: 100 mL.min\textsuperscript{-1} and column flow rate: 1 mL.min\textsuperscript{-1}. Helium gas with a purity of 99.99% was used as the carrier gas. The EOs components were identified using the method described in our previous report (17).

**Evaluation of the antibacterial activity of EOs.** 96-well plate microdilution method was used for determining the growth inhibitory effect of EOs against target bacteria with slight modification (15, 18). New cultured bacterial colonies (overnight culture) were suspended in Muller Hinton broth to reach $1.5 \times 10^7$ CFU/mL to reach the level of 0.5 McFarland turbidity. Then 20 μL of the bacterial suspension was added to each well using an 8-channel pipette.

A serial dilution of each EO was prepared by dissolving in Muller Hinton Broth (containing 0.5% DMSO) in a concentration range of 10.00-0.39 mg.mL\textsuperscript{-1}. By the addition of 80 μL form serial dilutions to each well, the concentration of EOs eventually fixed at 8.00, 4.00, 2.00, 1.00, 0.50, 0.25, 0.13, 0.06, and 0.03 mg.mL\textsuperscript{-1}. Three control wells were considered in each plate, filled with 20 and 80 μL of the bacteria suspension and the Muller Hinton Broth (containing DMSO 0.5%). Treated plates were then incubated at 37°C for 24 h. The turbidity of each well was read at 630 nm by a plate reader (Synergy HTX Multi-Mode Reader, USA), and the growth of bacteria was calculated using Equation 1.

\[
\text{Growth} \% = \frac{\text{Absorption of treated wells} \times 100}{\text{Absorption of control groups}}
\]

**Statistical methods.** Antibacterial tests were performed in triplicates. For calculation of means, standard deviations, and drawing charts, Excel software (Version 2010, Microsoft Corporation, USA) was used. IC\textsubscript{50} of the EOs was calculated using CalcuSyn software (Free version, BIOSOFT, UK). For comparing determined IC\textsubscript{50} of the EOs together, independent sample t-test and one-way ANOVA using SPSS software (Version 22, SPSS Inc, USA) were performed. In this study, a confidence interval of 95% (CI 95%) was considered.

**RESULTS**

**GC-MS analysis.** The five major constituents of each EO with their retention times and retention indices are listed in Table 1. The most abundant components for EOs were as follow; ADEO: p-allylanirole (67.62%), AGEO: p-cymene (20.81%) and α-phellandrene (20.75%), CLEO: limonene (61.83%),

*Retention Time; †Retention index

CSEO: limonene (71.26%), CZE0: cinnamaldehyde (62.04%), and ZOE0: zingiberene (30.28%).

Effect of the EOs on the growth of bacteria. The effect of ADEO at different concentrations (0.03-8.00 mg.mL⁻¹) on the targeted bacterial growth is depicted in Fig. 1. The best result was observed at a concentration of 8.00 mg.mL⁻¹ against S. aureus; the growth was reduced to ~17%, while K. pneumoniae, P. aeruginosa and E. coli were decreased to 36, 47 and 69%, respectively. From the literature, MIC of ADEO on S. aureus and E. coli were reported as 1.25 and 2,50 mg.mL⁻¹ (19). Moreover, its zone of inhabitation in the disk diffusion approach was reported as 8 mm for E. coli and 10 mm for S. aureus (8).

Fig. 2 shows the antibacterial activity of AGEO at various concentrations. The highest antibacterial activity was achieved at 8.00 against S. aureus, with inhibition in 34% growth. However, other bacterial growth was 54, 61, 73% for P. aeruginosa, K. pneumoniae and E. coli, respectively. Some reports on the MIC of ADEO against many bacteria have been found; For example, E. coli 1.25 mg.mL⁻¹, P. aeruginosa 1.5 mg.mL⁻¹, and S. aureus 0.62 mg.mL⁻¹ (20).

In another study, the MIC of AGEO on K. pneumoniae was reported as >10 mg.mL⁻¹ (21).

Results of the growth inhibitory effect of CLEO on some bacteria are demonstrated in Fig. 3. With the maximum growth of 14%, S. aureus was more affected after 24 h exposure with CLEO at a concentration of 8.00 mg.mL⁻¹; observed growth for three other bacteria was ~60%. Antibacterial effect (MIC) of CLEO on E. coli, K. pneumoniae, P. aeruginosa and S. aureus was reported previously. These values were 6.4, 12.8, 12.8 and 12.8 mg.mL⁻¹, respectively (22).

The antibacterial effect of CSEO is shown in Fig. 4. Totally, by increasing the concentration of EO, the growth of bacteria was reduced. At the highest level (8.00 mg.mL⁻¹), the growth of S. aureus, E. coli, P. aeruginosa and K. pneumoniae decreased to 13%, 57%, 43% and 35%, respectively. Like the previously mentioned EOs, S. aureus was more susceptible than other examined bacteria. Reviewing the literature, MIC of CSEO against S. aureus, K. pneumoniae and E. coli was reported as 0.062, 0.25, and 0.12 mg.mL⁻¹ (23). The related value for P. aeruginosa was 0.75 mg.mL⁻¹ (24).

After 24 h exposure with CZE0 (8.00 mg.mL⁻¹), the growth of bacteria had a substantial difference from each other (see Fig. 5). For instance, the observed growth for S. aureus was around 15%, while this amount for K. pneumoniae was 71%. This value for the other bacteria falls between those values (P. aeruginosa: 53% and E. coli: 40%). Antibacterial effect (MIC mg.mL⁻¹) of CZE0 on such bacteria, i.e., E. coli (1.6), K. pneumoniae (3.2), P. aeruginosa (0.8), and S. aureus (3.2) was reported previously (22).

As shown in Fig. 6, only the growth of K. pneumoniae decreased to <50% after treatment with ZOE0. E. coli, with a growth of 74%, was more resistant than others. In previously published papers, MIC of ZOE0 on targeted bacteria, including P. aeruginosa 31.25, S. aureus 7.81, E. coli 62.5 (25), and K. pneu-

*moniae* 20 (26) were reported.

In Table 2, IC$_{50}$s (with lower and upper confidence limits: LCL and UCL) of the EOs against four human pathogens are summarized.

### DISCUSSION

IC$_{50}$ of four EOs on *S. aureus* was around 2 mg mL$^{-1}$. CSEO (1.0), CLEO (1.3), ADEO (1.9), and CZEO (2.9). Their IC$_{50}$ is not significantly different from each other (one-way ANOVA, sig > 0.05), but substantially better than AGEO and ZOEO (one-way ANOVA, sig < 0.05). *S. aureus* is Gram-positive cocci, which is usually found in the nasal cavity and on the skin. Although most *S. aureus* strains often act as normal flora of the human microbiota, it can become an opportunistic pathogen, a common cause of various infections, such as skin infections and food poisoning. *S. aureus* is one of the most common reasons for hospital-acquired infections and is usually the cause of wound infections following surgery (27, 28).

Effect of CZEO on *E. coli* was significantly better than the other examined EO (one-way ANOVA, sig <

0.05); IC₅₀ (LCL-UCL): 1.0 (0.5-2.0) mg/mL 1. However, the calculated IC₅₀ for ZOEO (189.8) and AGEO (101.9) differ substantially against this bacterium, but were also larger than the total IC₅₀ calculated in this study. E. coli is a Gram-negative, facultative anaerobe rod and a genus of Enterobacteriaceae. Most strains of E. coli are harmless and are part of the normal microbiota of the gut. Still, some strains (pathotypes) can cause severe infections in humans, usually through food contamination. E. coli is one of the most important bacteria in a hospital and community-acquired infections in humans. Fecal–oral transmission is the usual route through which pathotypes of the E. coli cause disease (29, 30).

CSEO has the lowest IC50 (4.7 mg/mL) against P. aeruginosa, this amount significantly better than AGEO (19.1), CLEO (16.2), and ZOEO (14.0) (one-way ANOVA, sig < 0.05). Furthermore, ADEO and CSEO with IC₅₀ of 6.1 and 7.2 mg/mL, respectively, showed good antibacterial activity, and their IC₅₀ were not significantly different from CSEO (one-way ANOVA, sig > 0.05). P. aeruginosa is a Gram-negative rod found in soil, water, and skin flora. An opportunistic microorganism in which severe infection often occurs during existing diseases or conditions, such as damaged tissues, cystic fibrosis, and wound burns, is common in acute illness, especially hospital-acquired infections. Treatment of P. aeruginosa infections can be difficult due to its natural resistance to antibiotics (multidrug-resistant pathogen) (31, 32).

The lowest observed IC₅₀ (LCL-UCL) against K. pneumoniae was related to ADEO: 1.3 (1.0-1.8) mg/mL 1. ZOEO, CSEO, AGEO, CLEO and ZOEO with IC₅₀ of 3.0, 5.8, 22.2, 33.1 and 42.9 mg/mL 1 were situated in other ranks. K. pneumoniae is a Gram-negative rod, facultatively anaerobic, found in the intestine normal flora. K. pneumoniae can cause destructive changes to the human lungs if aspirated, resulting in bloody sputum. In recent years, Klebsiella species have become important pathogens in hospital-acquired infections (33, 34).

In other researches, MIC of ADEO on S. aureus and E. coli were reported as 1.25 and 2.50 mg/mL (19). MIC of CSEO on E. coli, K. pneumoniae, P. aeruginosa and S. aureus was 6.4, 12.8, 12.8 and 12.8 mg/mL, respectively (22). MIC of CSEO against S. aureus, K. pneumoniae and E. coli was reported as 0.062, 0.25 and 0.12 mg/mL (23). The related value for P. aeruginosa was 0.75 mg/mL (24). MIC of ZOEO on targeted bacteria, including P. aeruginosa 31.25, S. aureus 7.81, E. coli 62.5 (25), and K. pneumoniae 20 (26) were reported.

CONCLUSION

Antibacterial activity of six EOs was investigated in a quantitative approach on four important human pathogens. CSEO (IC₅₀ 1.0 mg/mL), CSEO (1.0 mg/mL), CSEO (4.7 mg/mL), and ADEO (IC₅₀ 1.3 mg/mL) were the most effective against S. aureus, E. coli, P. aeruginosa and K. pneumoniae, respectively. These EOs could be used for developing inexpensive, potent, and green antibacterial agents.
